

Aggregation

 javatpoint.com/dbms-aggregation

In aggregation, relation between two entities is treated as a single entity. In aggregation, relationship with its corresponding entities is aggregated into a higher level entity.

For example: Center entity offers the Course entity act as a single entity in the relationship which is in relationship with another entity visitor. In the real world, if a visitor visits a coaching center then he will never enquire about the Course only or just about the Center rather he will ask enquire about both.
